

*AACHENER VERFAHRENSTECHNIK*

# Evaluation of Reaction Pathways for Next-Generation Biofuels

**Anna Voll & Wolfgang Marquardt**

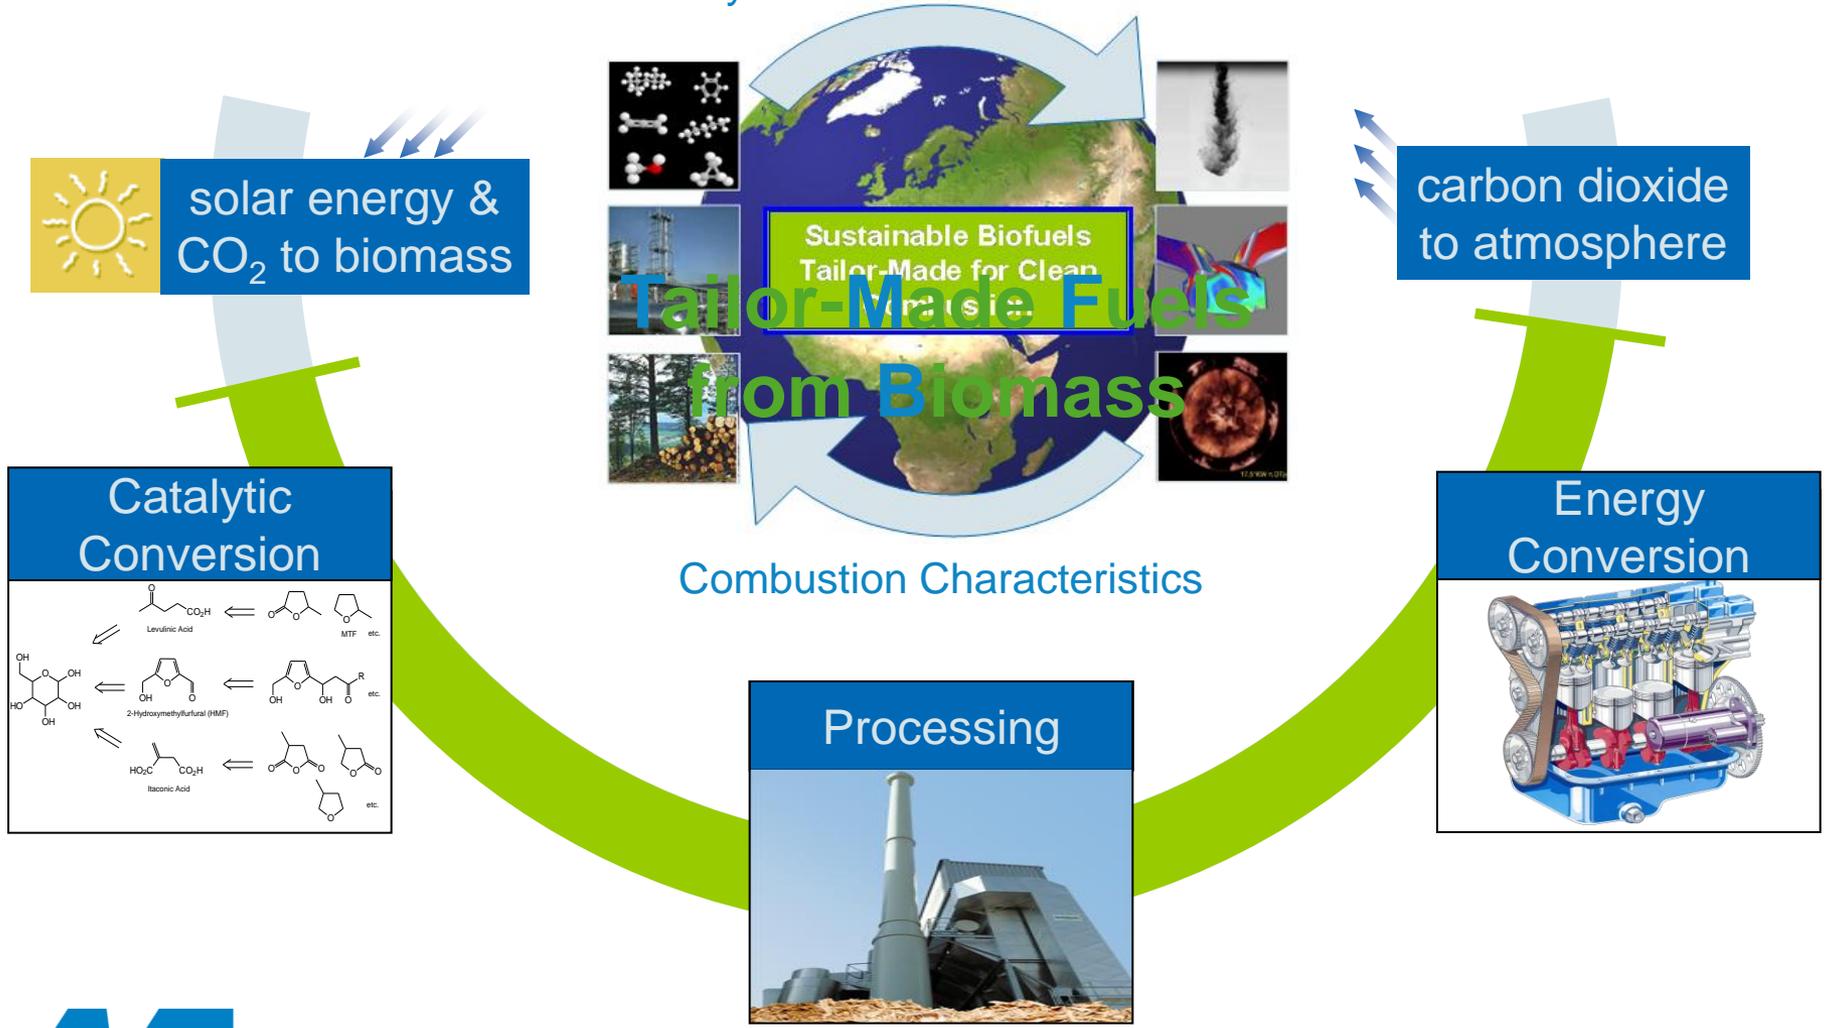

Aachener Verfahrenstechnik – Process Systems Engineering  
RWTH Aachen University, Germany

1<sup>st</sup> Brazilian BioEnergy Science  
and Technology Conference  
Campos do Jordão  
August 14 to 18, 2011

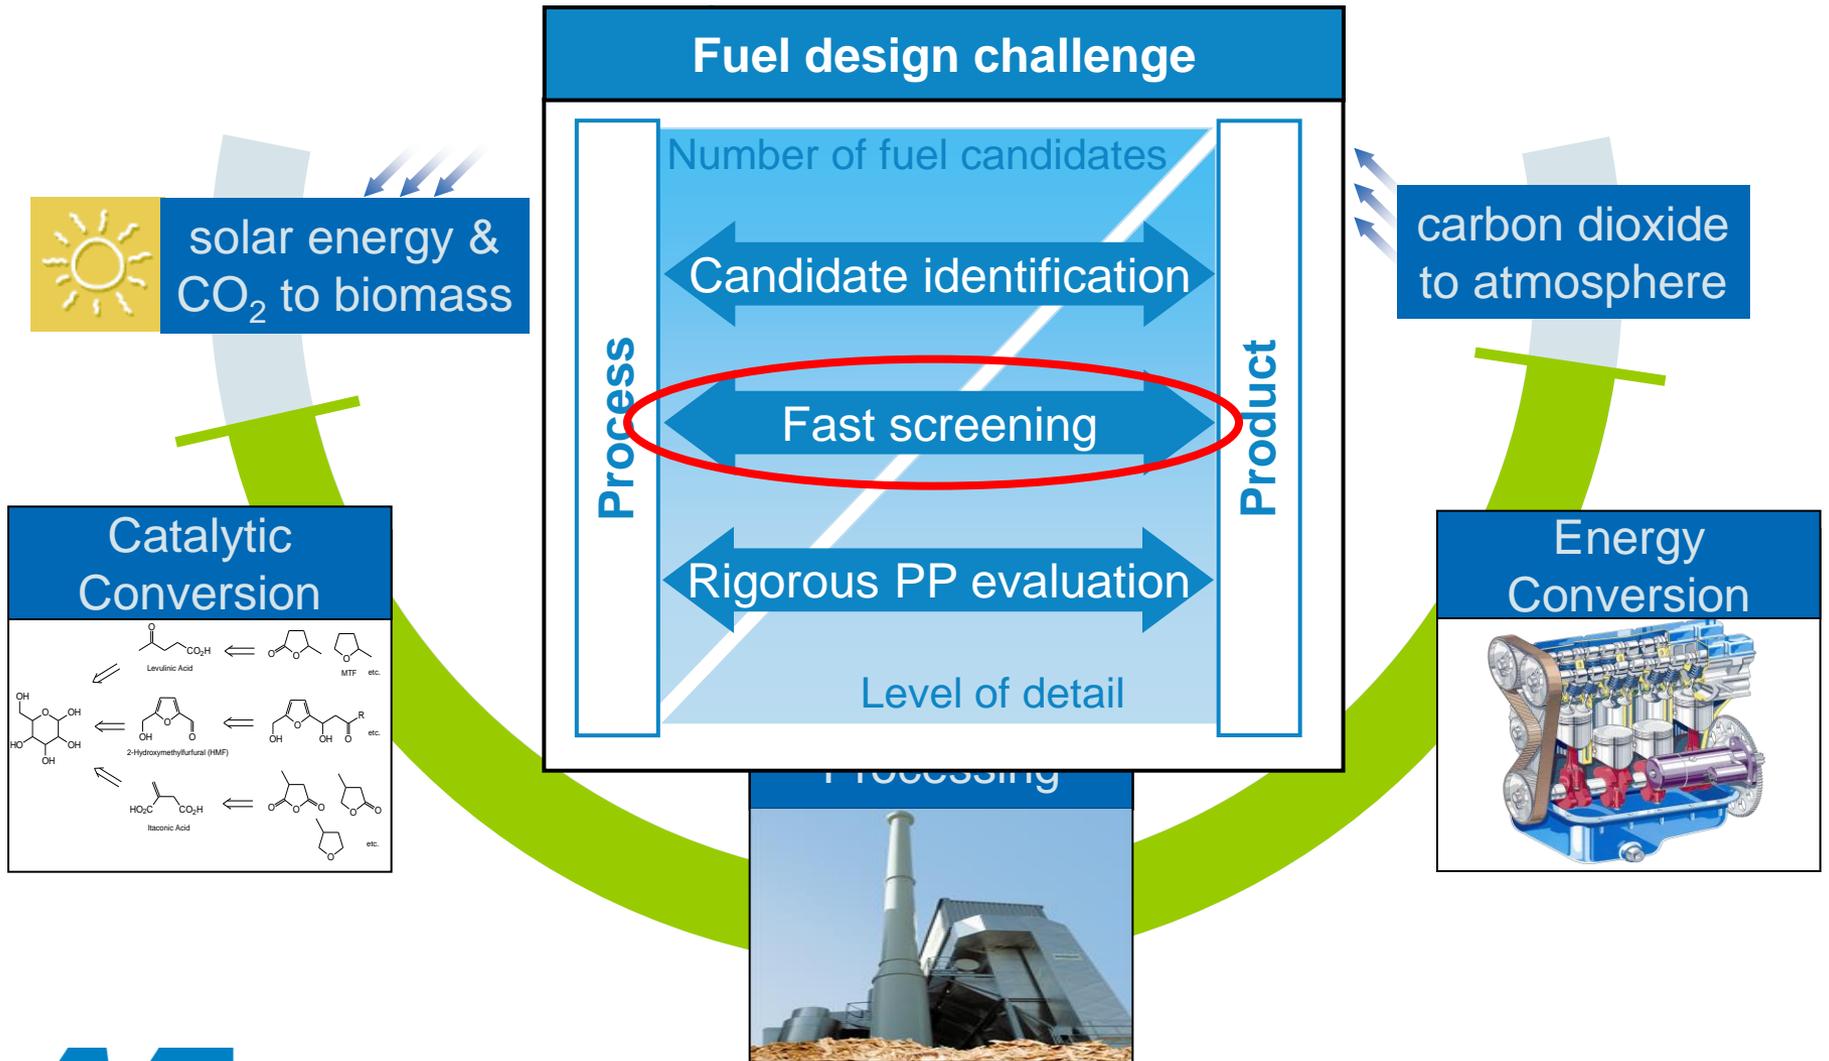

# TMFB Cluster of Excellence @ RWTH Aachen University

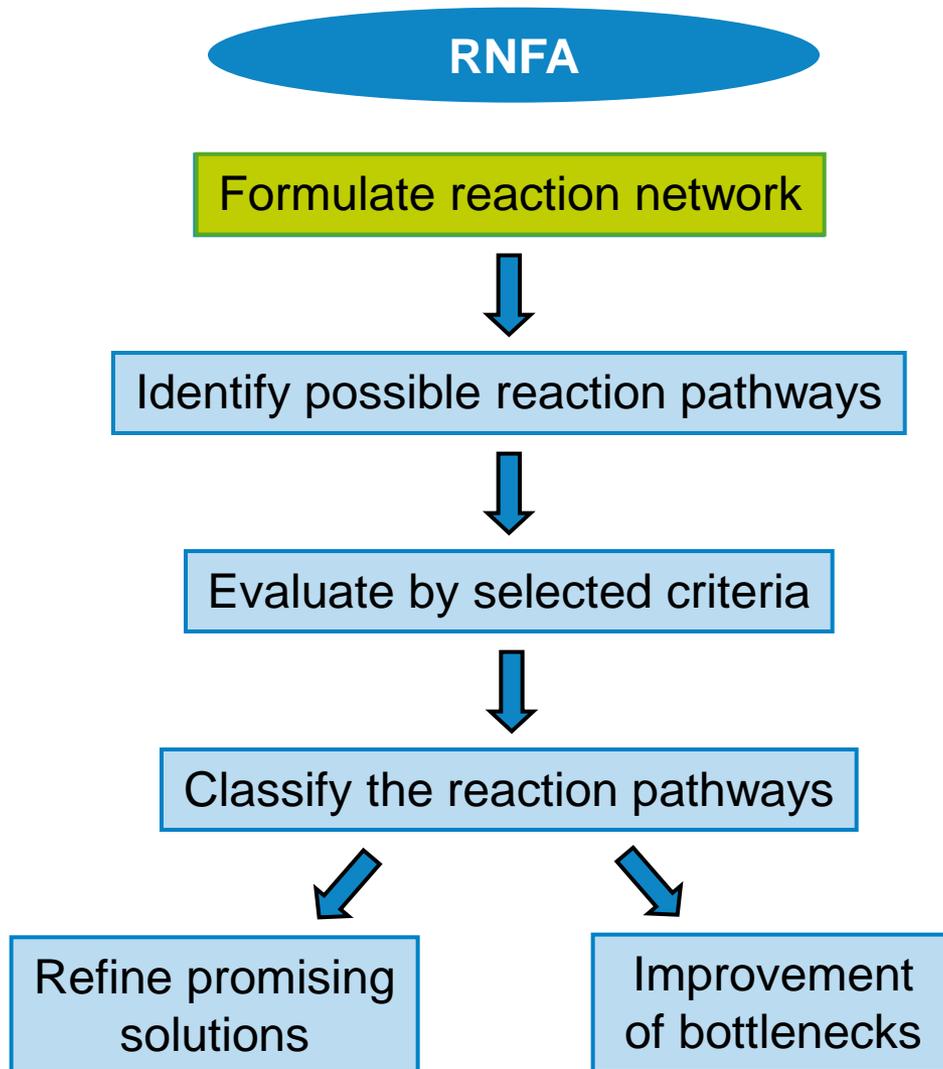

## Novel Synthesis and Production Routes

# TMFB Cluster of Excellence @ RWTH Aachen University

# Reaction Network Flux Analysis (RNFA)

## Representation of network:

- Nodes → molecules
- Arcs → reactions

## Network model:

$$A \cdot f = b$$

$$f_j \leq Y_j \sum_{k, k \neq j} v_k \cdot f_k \quad \forall j$$

$$f, b \geq 0$$

1

$A$  Matrix of stoichiometric coefficients

$f$  Flux vector

$b$  Production vector

$Y$  Yield coefficient

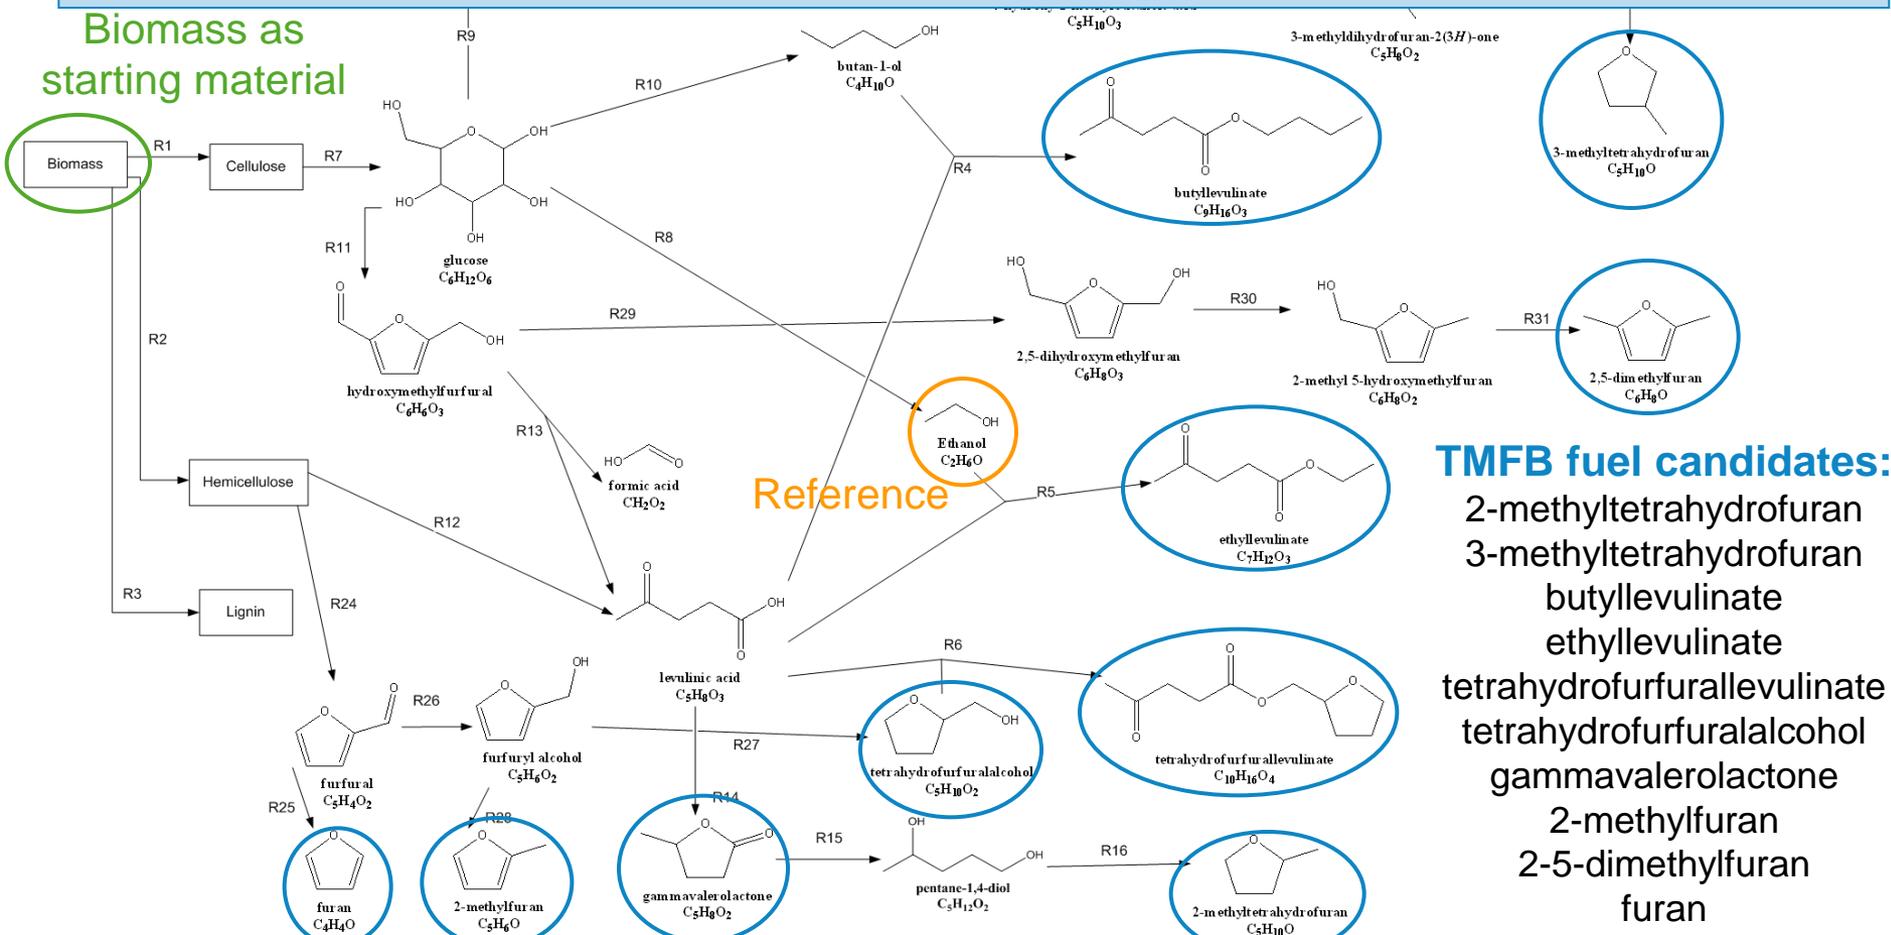

$v$  Stoichiometric coefficient

# Reaction Network for Fuel Candidates

## Case study: Comparison of 10 TMFB fuel candidates

- Same amount of fuel energy should be produced.
- Reference: production of 100 000 t/yr cellulosic ethanol.

Biomass as starting material

# Reaction Network Flux Analysis (RNFA)

## Process Screening

Formulate reaction network

Identify all possible reaction pathways

Evaluate by additional criteria

Classify the reaction pathways

Refine promising solutions

Improvement of bottlenecks

Mass balance related criteria:

- **Product yield**
- By-product formation
- Need of additional reactants
- Carbon efficiency
- Energy efficiency

# Reaction Network Flux Analysis (RNFA)

## Process Screening

Formulate reaction network

Identify possible reaction pathways

Evaluate by additional criteria

Classify the reaction pathways

Refine promising solutions

Improvement of bottlenecks

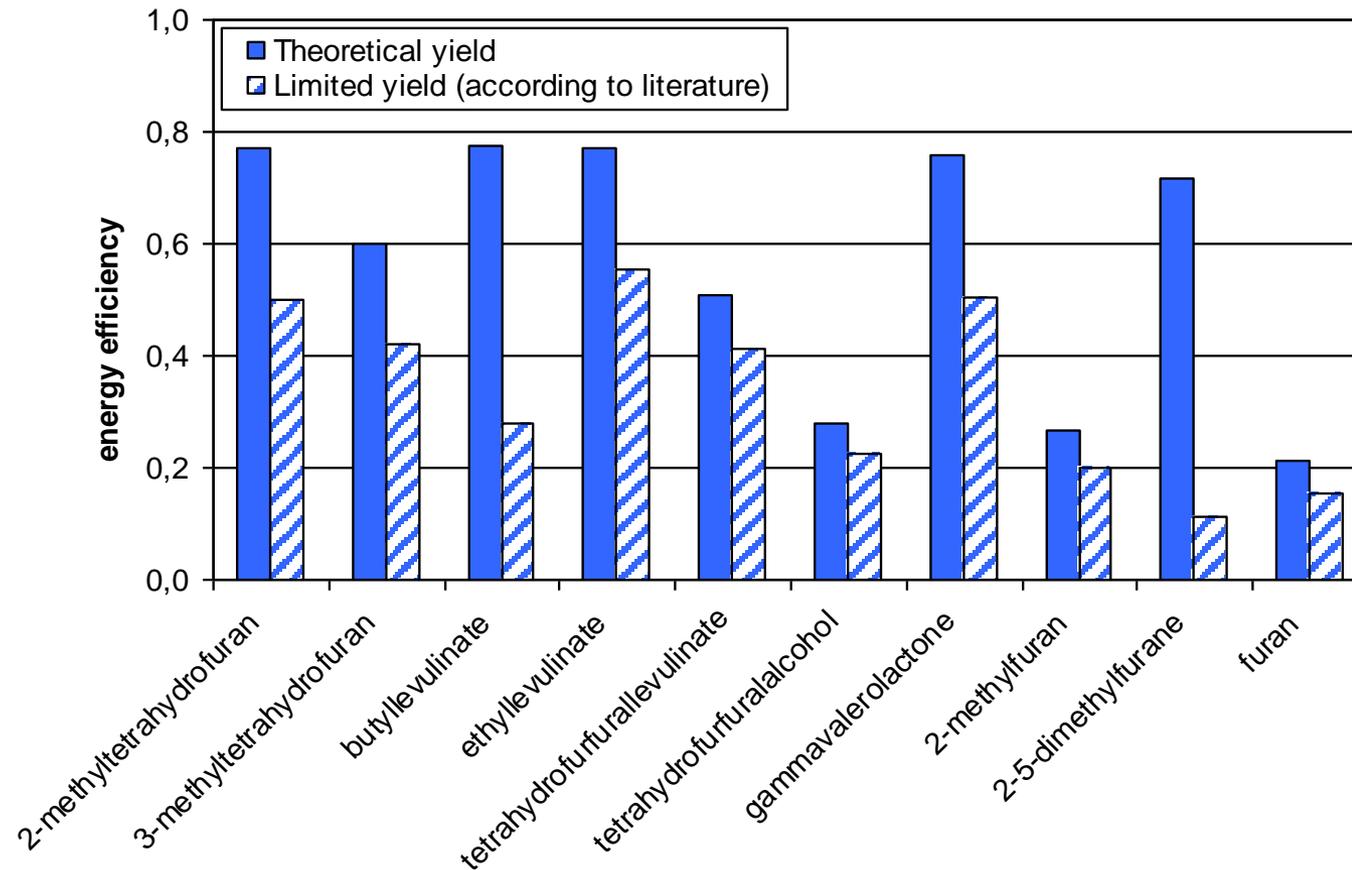

Energy efficiency:

$$\eta^E = \frac{\text{“energy in product”}}{\text{“energy in substrate”}}$$

$$= \frac{b_{\text{target}} H_{\text{com, target}}}{\sum x_{\text{in}} H_{\text{com, in}}}$$

①

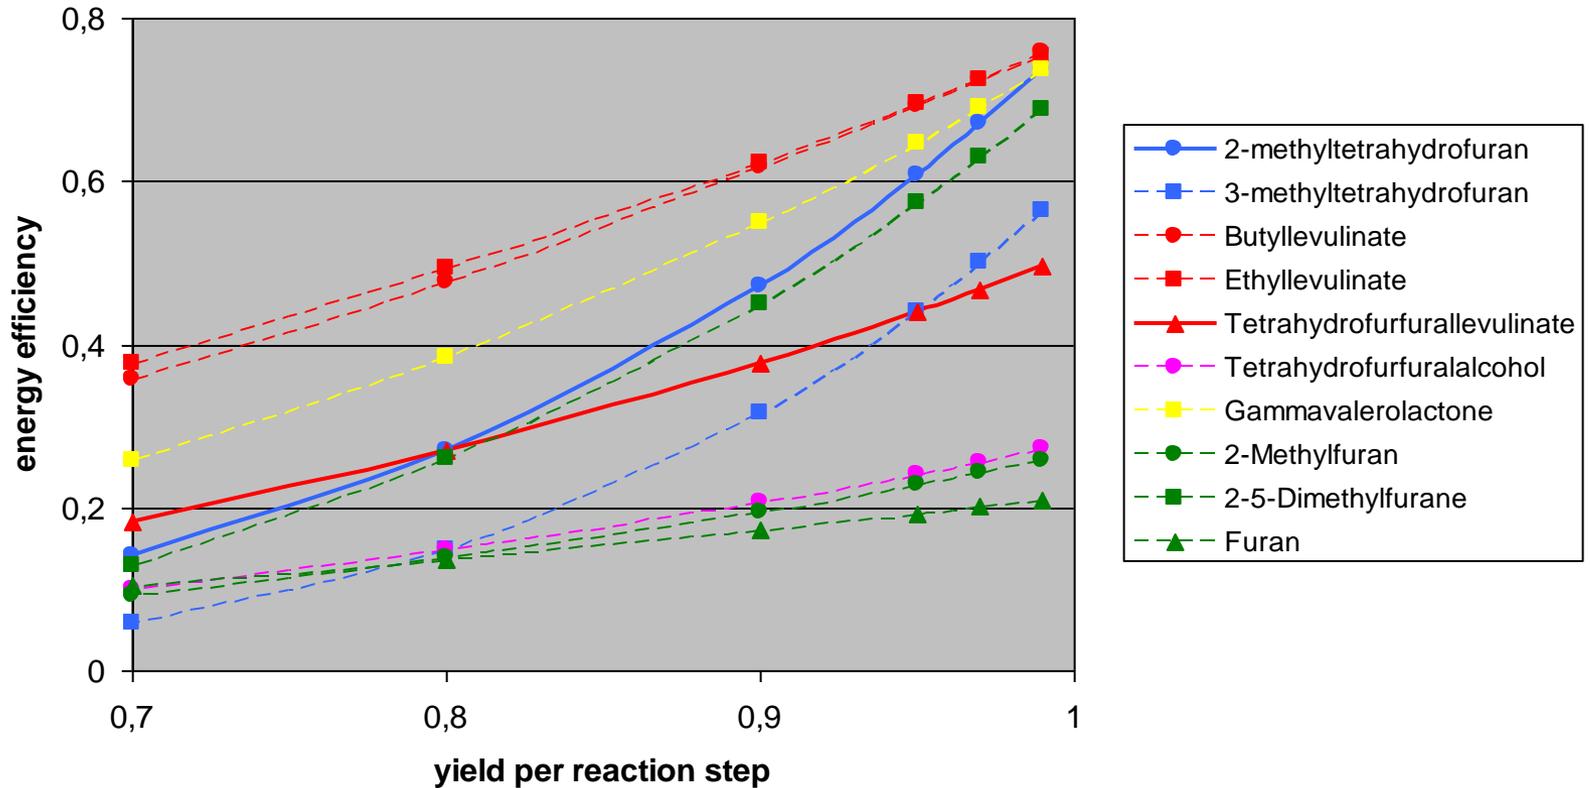

# Comparison of Energy Efficiencies

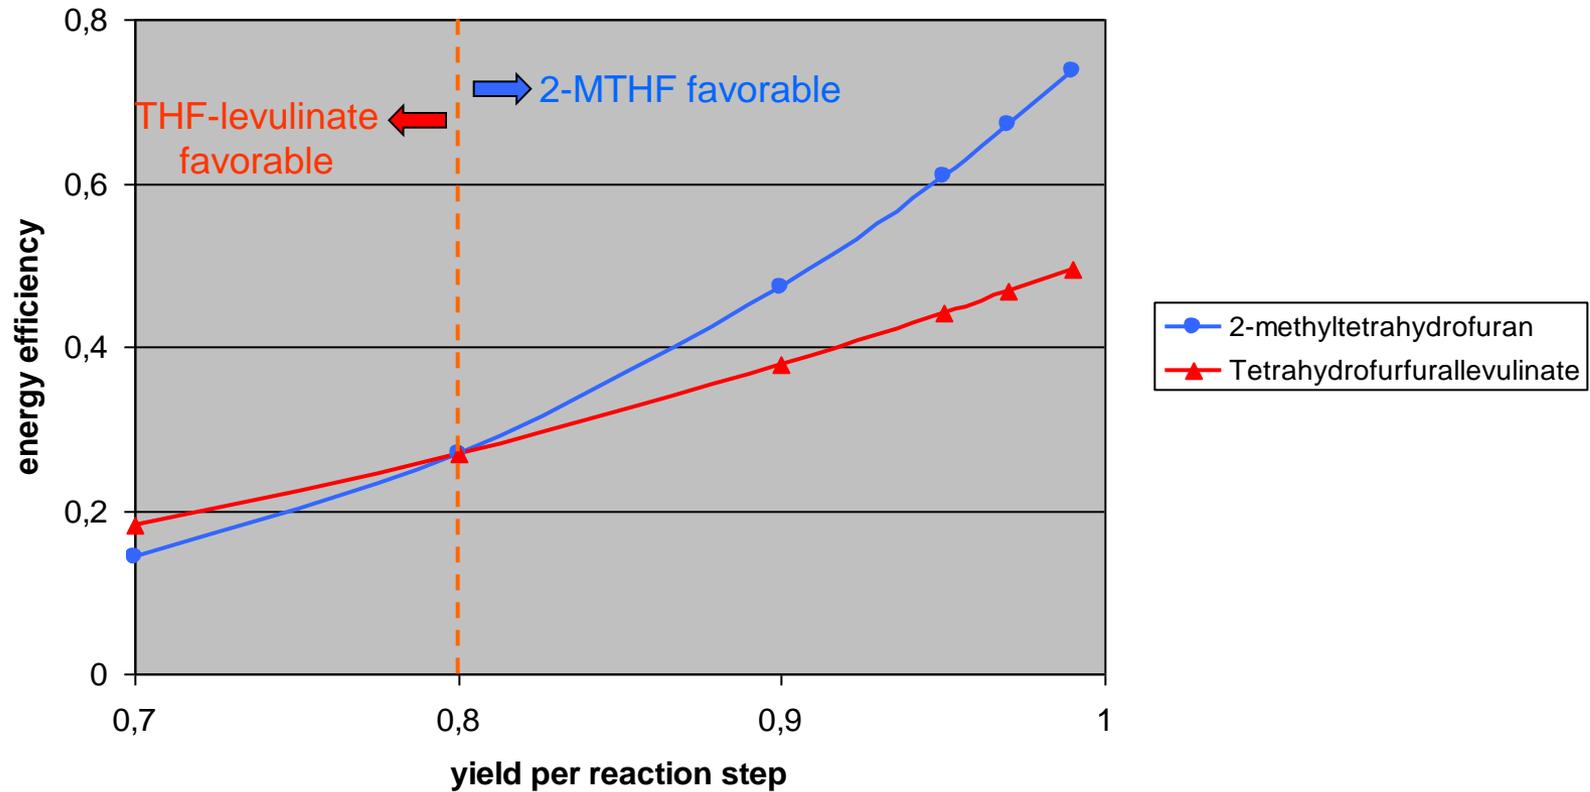

## Reaction yields

- have a significant effect on the evaluation results,
- but are often subject to significant uncertainty.

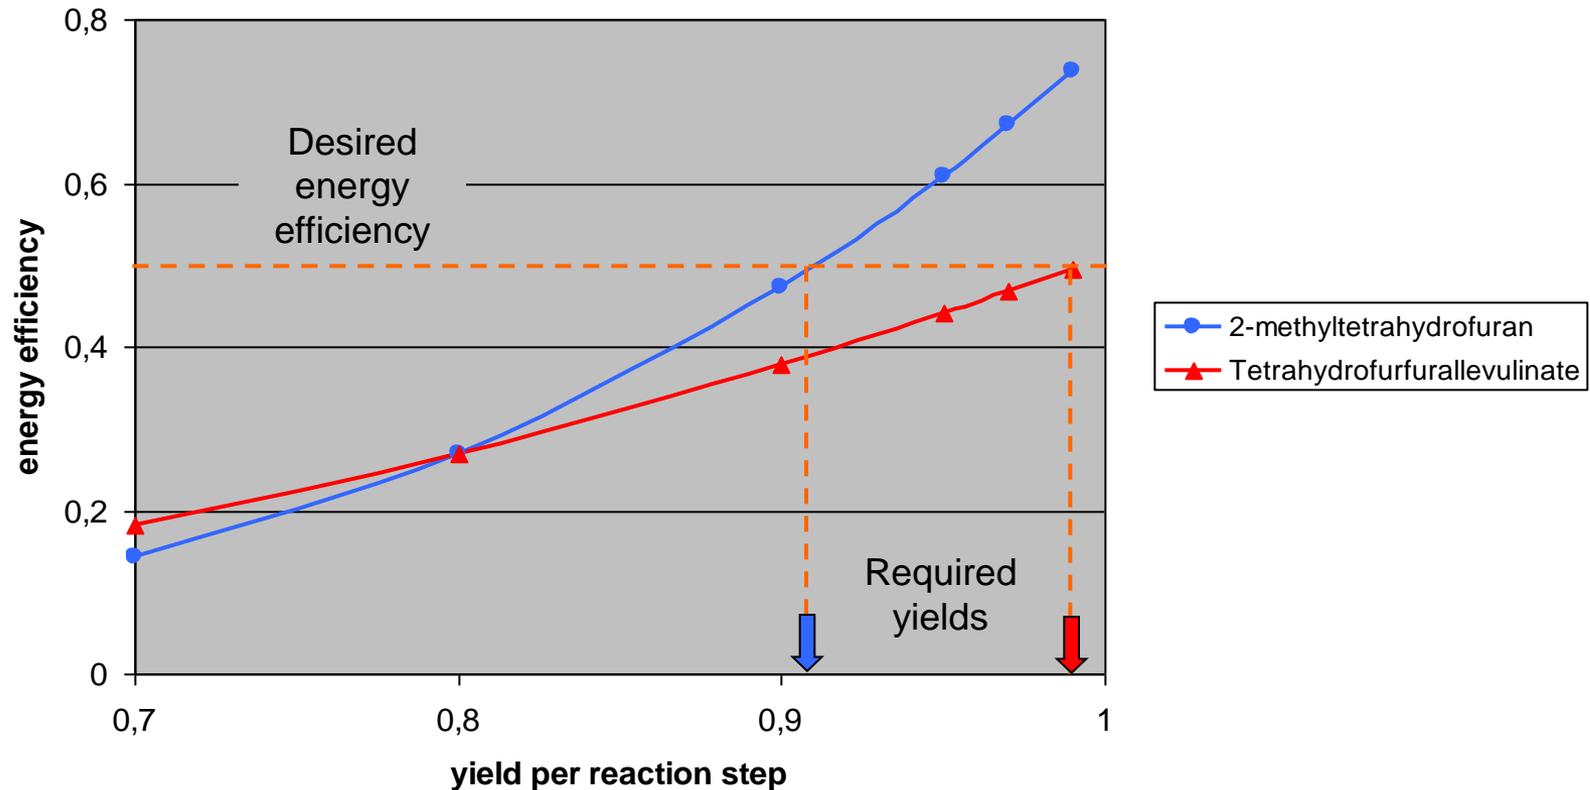

# Variation of Yield Coefficients

# Variation of Yield Coefficients

# Variation of Yield Coefficients

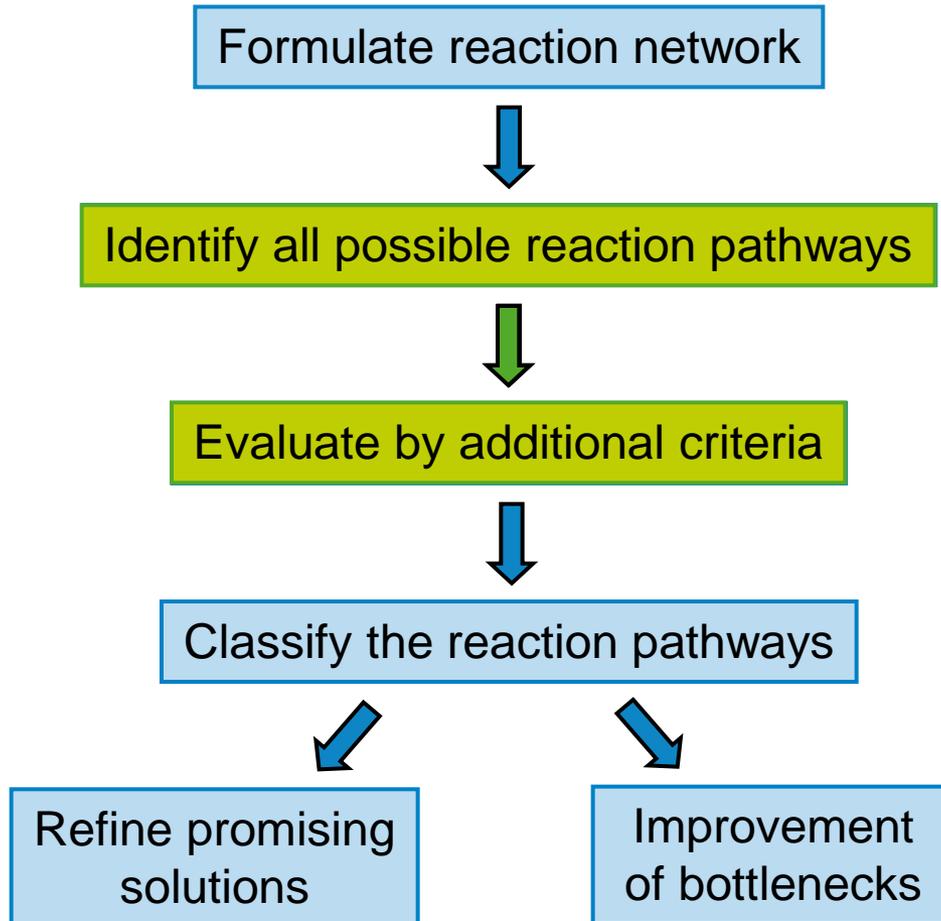

## Targets

- can be set based on yield sensitivity analysis.

# Reaction Network Flux Analysis (RNFA)

## Process Screening

## Mass balance related criteria:

- Product yield
- By-product formation
- Need of additional reactants
- Carbon efficiency
- Energy efficiency

# Total Annualized Cost (TAC)

- TAC are composed of two parts:
  - Total raw material cost ( $C_{Raw}$ )
  - Investment cost (IC in M\$)\*
- Realization within RNFA:

$$TAC = C_{Raw} + \frac{IC \cdot i}{1 - (1+i)^{-n}}$$

$$C_{Raw} = \sum_{i=1}^s (A_I f_I)_i M_i C_i$$

$$IC = 3 \cdot 10^6 (\Delta E)^{0.84}$$

②

$i$  Interest rate (8%)

$n$  Plant lifetime (10 years)

$C$  Raw material prices

$\Delta E$  Energy loss

# Environmental Impact (EI)

- Eco-Efficiency Analysis\* covering the following aspects:
  - Energy consumption (EC)
  - Resource consumption (RC)
  - CO<sub>2</sub> emission impact (Em)
  - Toxicity potential (TP)
- Adapted to be integrated in RNFA:

$$EI = \frac{EC}{\|EC\|_{\infty}} + \frac{RC}{\|RC\|_{\infty}} + \frac{Em}{\|Em\|_{\infty}} + \frac{TP}{\|TP\|_{\infty}}$$

3

$$EC = \frac{\Delta E}{M_{\text{target}} b_{\text{target}}}$$

$$RC = \frac{\sum_{i=1}^s (A_1 f_1)_i M_i}{M_{\text{target}} b_{\text{target}}}$$

$$Em = \frac{M_{CO_2} b_{CO_2}}{M_{\text{target}} b_{\text{target}}}$$

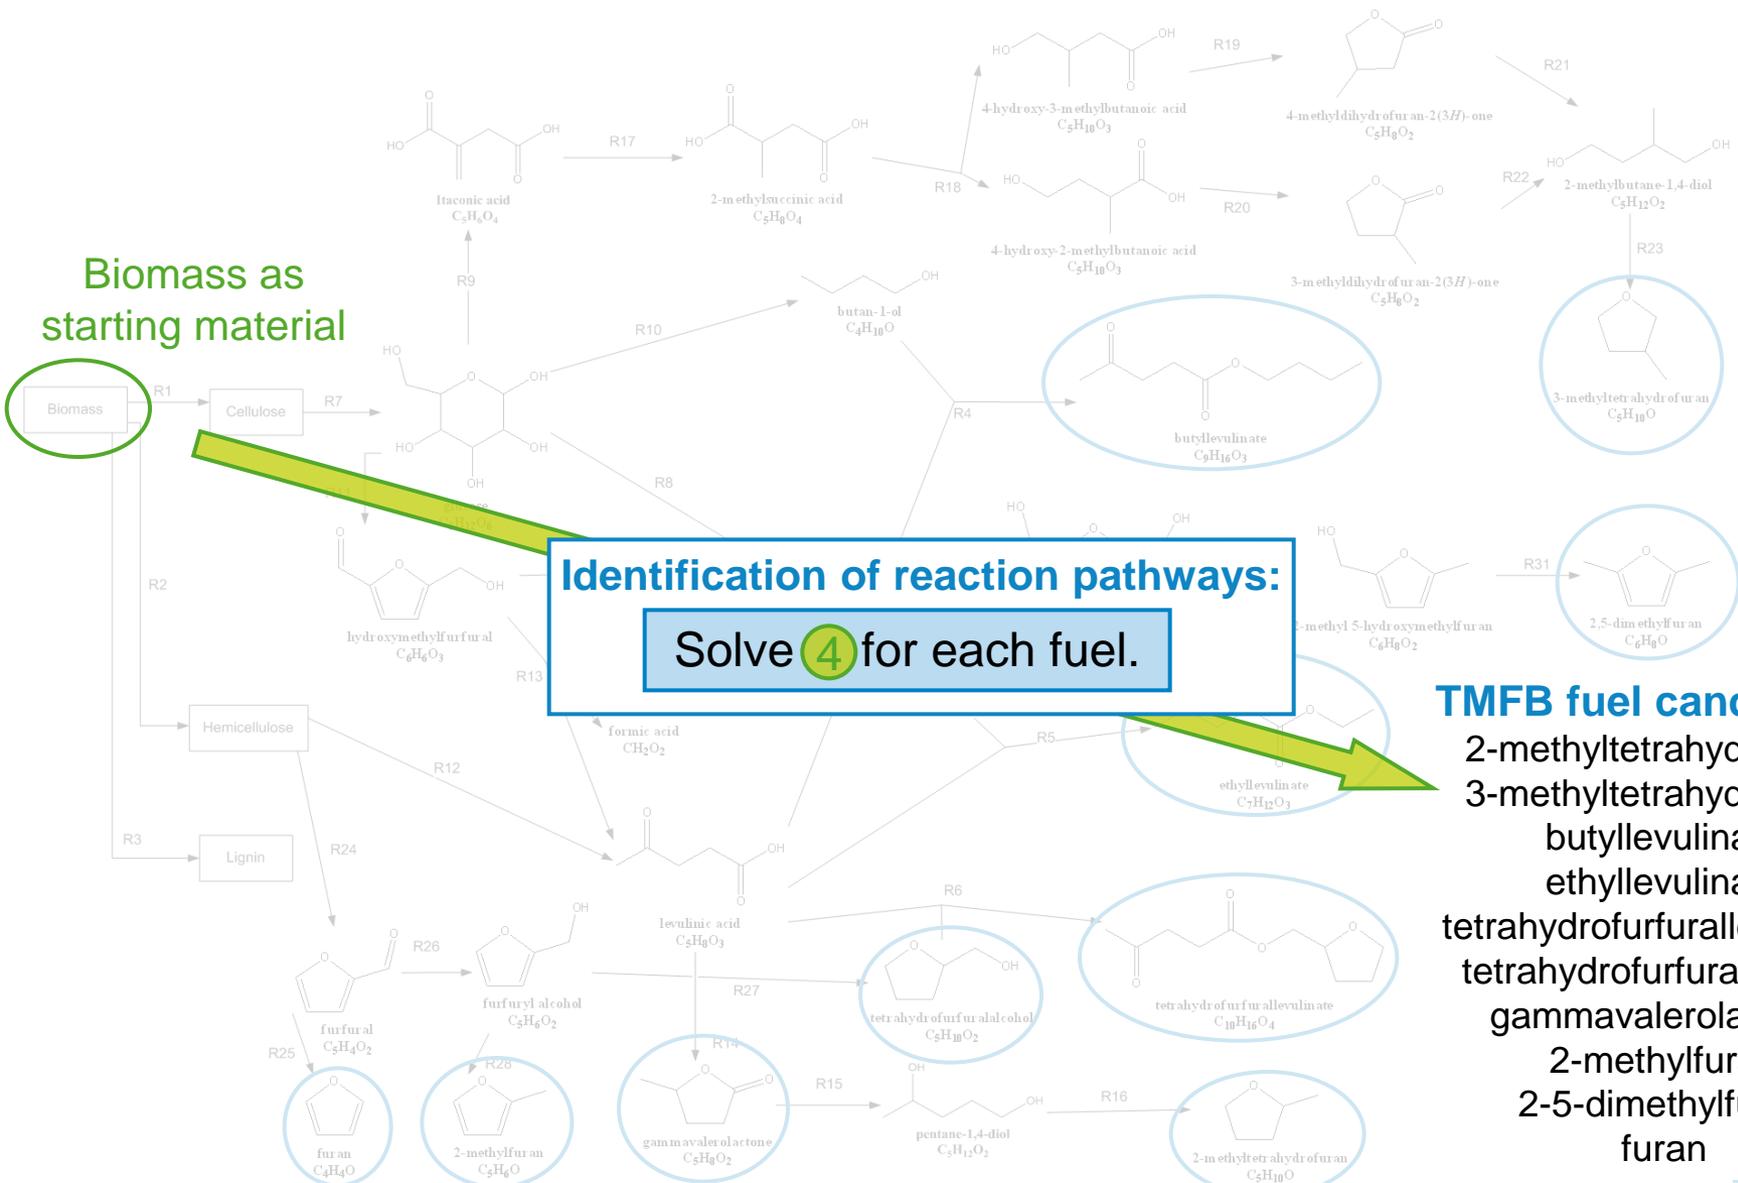

$$TP = M_{\text{target}} b_{\text{target}} TS_{\text{target}}$$

***M*** Molar mass  
***TS*** Toxicity scale

# Reaction Network for Fuel Candidates

Biomass as starting material

**TMFB fuel candidates:**

- 2-methyltetrahydrofuran
- 3-methyltetrahydrofuran
- butyllevulinate
- ethyllevulinate
- tetrahydrofurallevulinate
- tetrahydrofuralalcohol
- gamma-valerolactone
- 2-methylfuran
- 2-5-dimethylfuran
- furan

# Reaction Network Flux Analysis (RNFA)

---

## Process Screening

Formulate reaction network

Identify all possible reaction pathways

Evaluate by additional criteria

Classify the reaction pathways

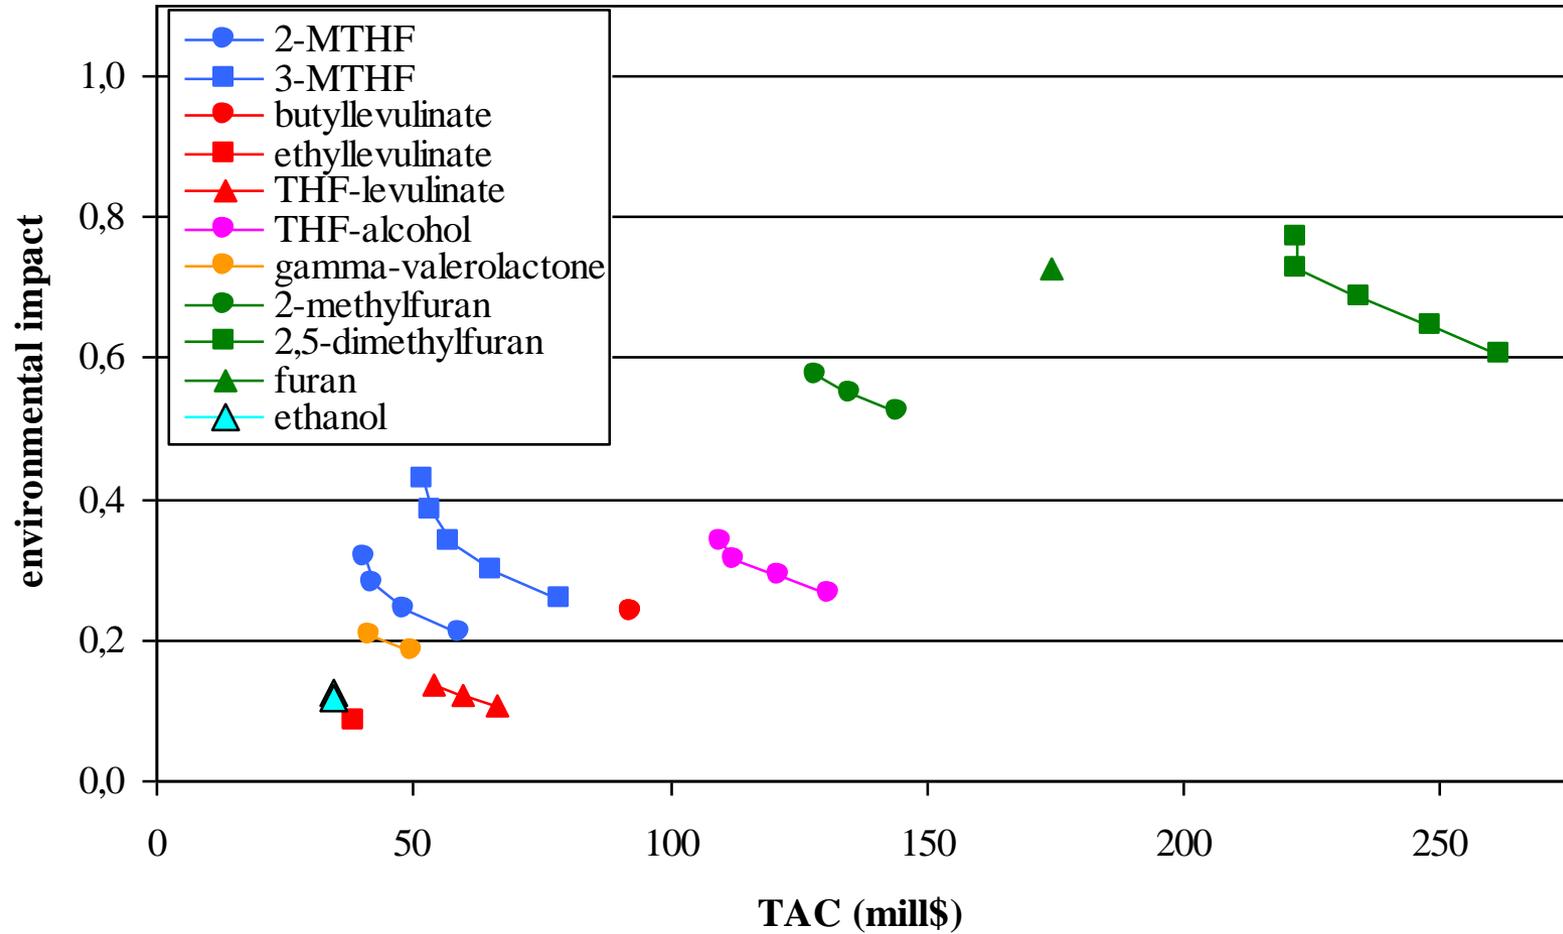

Refine promising solutions

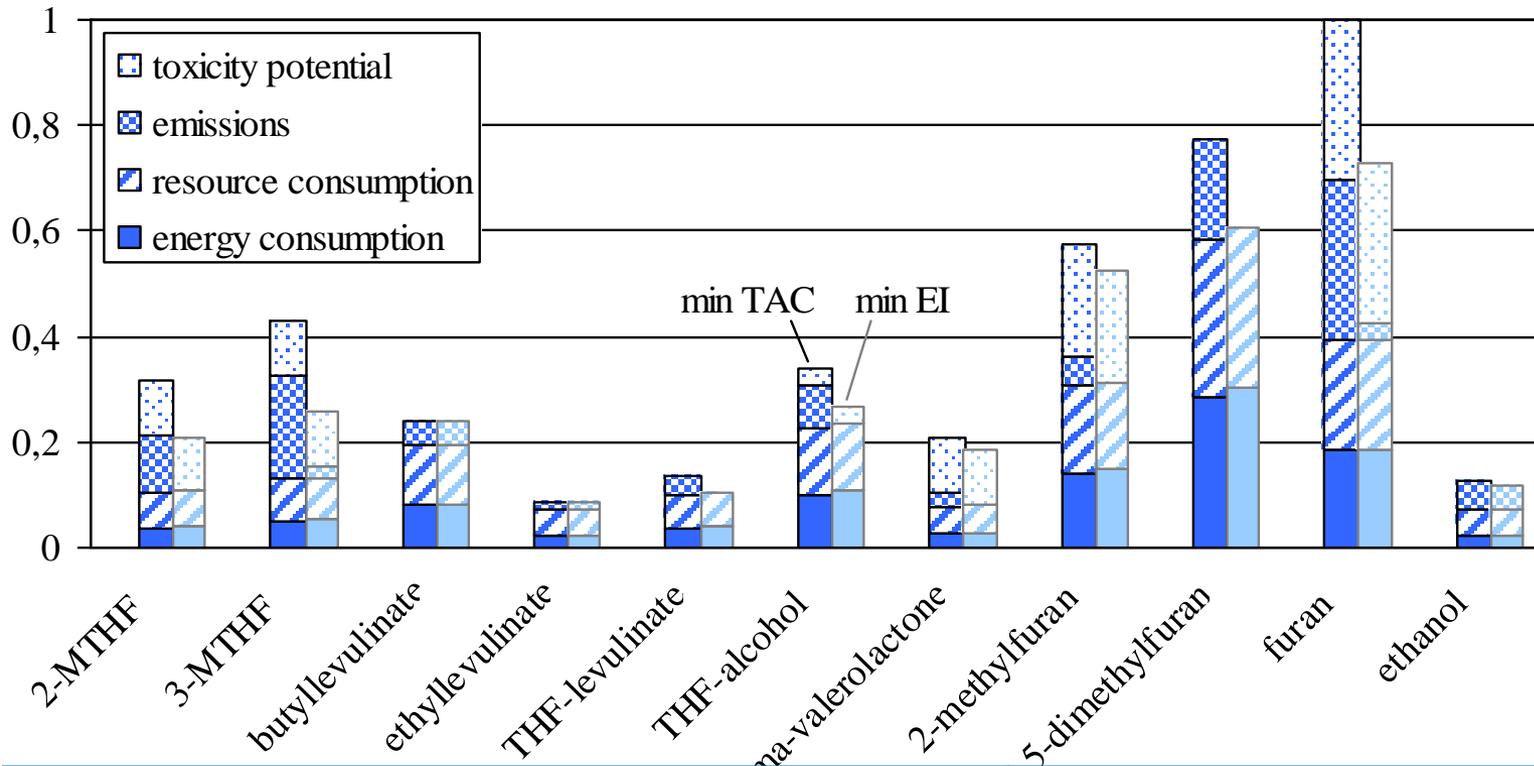

Improvement of bottlenecks

# Results – Pareto Fronts

# Results – Environmental Impact

## Hydrogen source trade-off:

- **min TAC:** Gasification of biomass residuals: higher CO<sub>2</sub> emissions
- **min EI:** External carbon neutral supply: higher energy/resources consumption and cost

# Reaction Network Flux Analysis (RNFA)

## RNFA

Formulate reaction network

Identify possible reactions

Evaluate by selected criteria

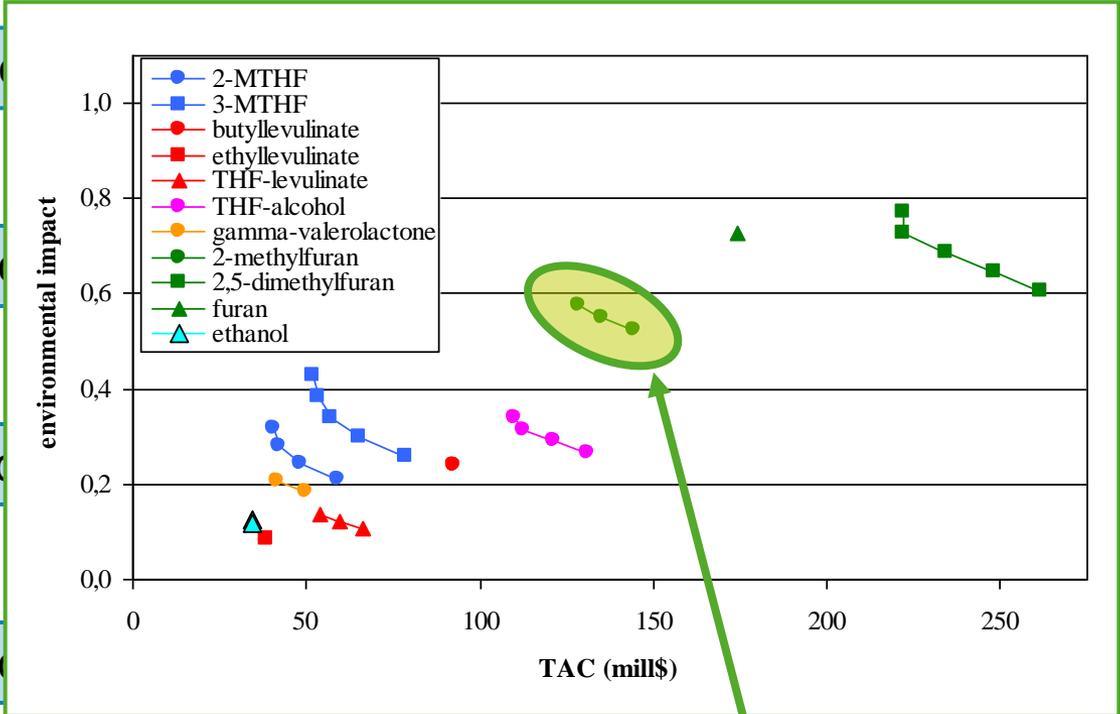

Classify the reactions

Refine promising solutions

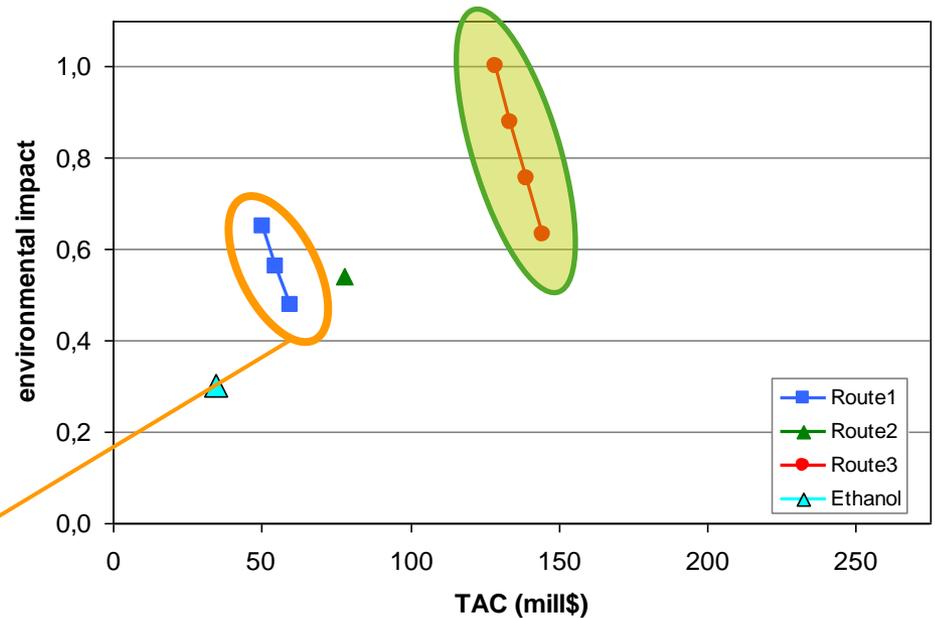

Improvement of bottlenecks

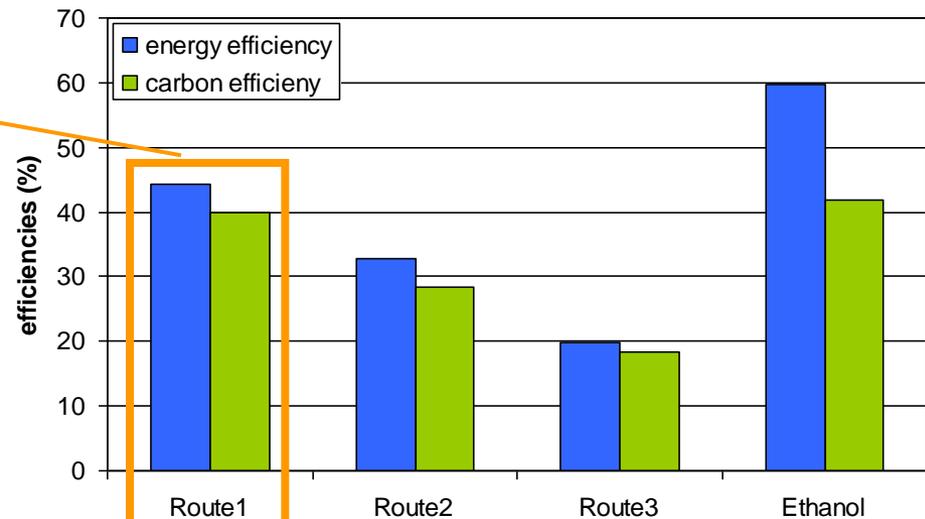

2-methylfuran – not an attractive fuel?

# Focus on 2-Methylfuran Synthesis

- Comparison of **3 catalytical concepts** for the production of 2-methyl-furan from biomass.
- Performance can be increased significantly by novel catalysis routes.
- 2-methylfuran is a promising fuel candidate!!

TMFB approach  
(Leitner group)

# Concluding Remarks

---

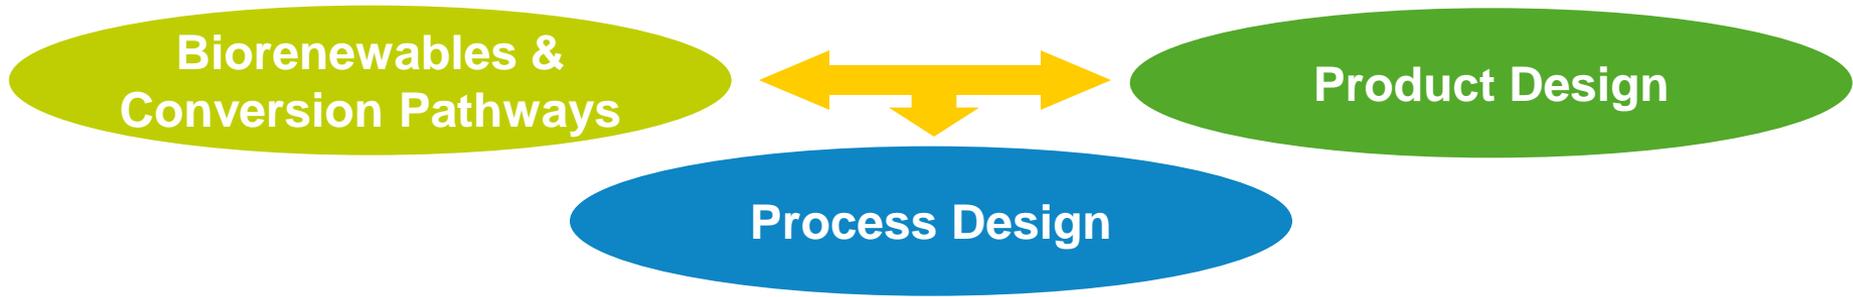

## Reaction Network Flux Analysis (RNFA)

- motivated by Metabolic Flux Analysis (Schilling & Palsson, 1998);
- enables an early screening of biofuel processes based on
  - the mass balances,
  - **economic** and **ecological** criteria;
- can be extended to a multi-criteria evaluation;
- can be integrated with product design (Hechinger et al., 2010).

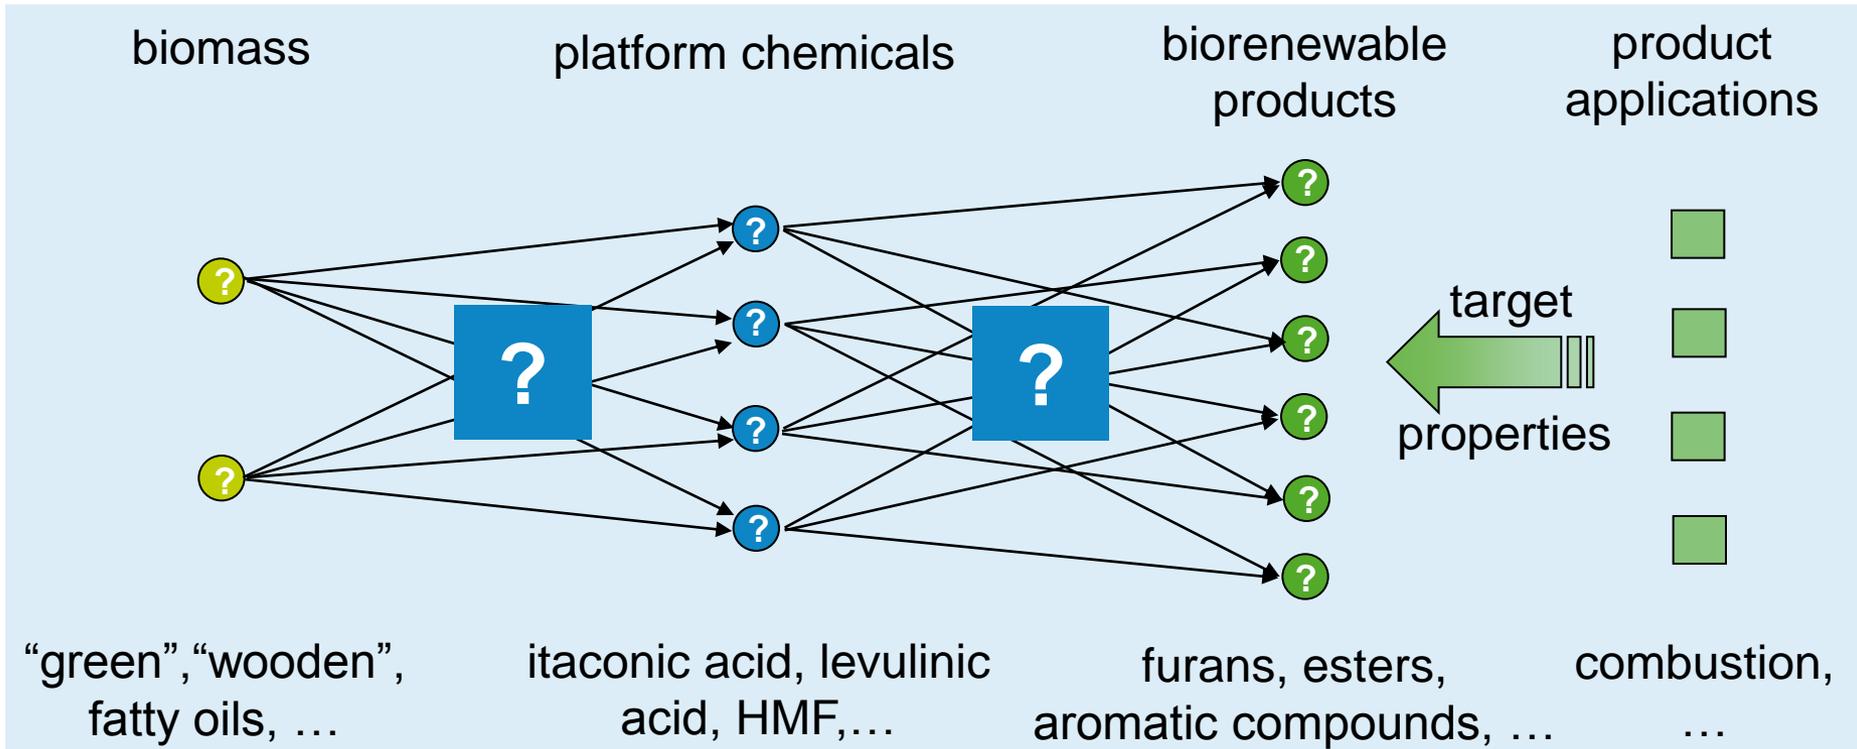

## Reaction Network Flux Analysis (RNFA)

- guides the discovery of accessible biofuels and research in catalysis
- forms the starting point for model-based process synthesis and process integration.
